# Anatomy for Dental Medicine

## Third Edition

### **Edited by**

Eric W. Baker, MA, MPhil  
Department of Basic Science and Craniofacial Biology  
New York University College of Dentistry  
New York, New York

### **Associate Editor**

Elisabeth K. N. Lopez, PhD  
Department of Basic Science and Craniofacial Biology  
New York University College of Dentistry  
New York, New York

### **Based on the work of**

Michael Schuenke, MD, PhD  
Institute of Anatomy  
Christian Albrecht University, Kiel

Erik Schulte, MD  
Institute of Functional and Clinical Anatomy  
Johannes Gutenberg University, Mainz

Udo Schumacher, MD, FRCPath, CBiol, FRSB, DSc  
Center for Experimental Medicine  
Institute of Anatomy and Experimental Morphology  
University Medical Center, Hamburg-Eppendorf

### **Illustrations by**

Markus Voll  
Karl Wesker

Title: Anatomy for dental medicine / editor, Eric W. Baker ; associate editor, Elisabeth K.N. Lopez ; based on the work of Michael Schuenke, Erik Schulte, Udo Schumacher ; illustrations by Markus Voll, Karl Wesker.

Description: Third edition. | New York : Thieme, [2020] | Includes index. | Summary: "Dental students/residents and other allied health students who deal with anatomy in the area of the head and neck need to master anatomy of those regions. Most of the atlases that are on the market cover whole body anatomy without the focus and additional details that these students require. Anatomy for Dental Medicine strikes an optimal balance between systemic and regional approaches to this complex anatomy, which suits both first-time student learner as well as anatomy review for the boards or specialty courses. The new edition continues to combine our award-winning, full-color illustrations with explanatory text and summary tables. The clinical correlations, multiple choice questions and explanations as well as an appendix on the anatomy of common dental anesthetic injections specifically support dental students. The new edition is updated with radiology images, new factual and clinical questions, and a general revision of content"— Provided by publisher.

Identifiers: LCCN 2019053817 | ISBN 9781684200467 (paperback) | ISBN 9781684200474 (ebook)

Subjects: MESH: Head—anatomy & histology | Dentistry | Neck—anatomy & histology | Atlas

Important note: Medicine is an ever-changing science undergoing continual development. Research and clinical experience are continually expanding our knowledge, in particular our knowledge of proper treatment and drug therapy. Insofar as this book mentions any dosage or application, readers may rest assured that the authors, editors, and publishers have made every effort to ensure that such references are in accordance with **the state of knowledge at the time of production of the book**.

Nevertheless, this does not involve, imply, or express any guarantee or responsibility on the part of the publishers in respect to any dosage instructions and forms of applications stated in the book. **Every user is requested to examine carefully** the manufacturer's leaflets accompanying each drug and to check, if necessary in consultation with a physician or specialist, whether the dosage schedules mentioned therein or the contraindications stated by the manufacturers differ from the statements made in the present book. Such examination is particularly important with drugs that are either rarely used or have been newly released on the market. Every dosage schedule or every form of application used is entirely at the user's own risk and responsibility. The authors and publishers request every user to report to the publishers any discrepancies or inaccuracies noticed. If errors in this work are found after publication, errata will be posted at [www.thieme.com](http://www.thieme.com) on the product description page.

Some of the product names, patents, and registered designs referred to in this book are in fact registered trademarks or proprietary names even though specific reference to this fact is not always made in the text. Therefore, the appearance of a name without designation as proprietary is not to be construed as a representation by the publisher that it is in the public domain.

This book, including all parts thereof, is legally protected by copyright. Any use, exploitation, or commercialization outside the narrow limits set by copyright legislation, without the publisher's consent, is illegal and liable to prosecution. This applies in particular to photostat reproduction, copying, mimeographing, preparation of microfilms, and electronic data processing and storage.

To my wonderful wife, Amy Curran Baker,  
and my awe-inspiring daughters, Phoebe and Claire. — E.W.B.

To my loving and supportive family, Leonardo,  
Penelope, and Ariadne, who never cease to inspire me. — E.K.N.L.

# Contents

Preface .....	XIII
Acknowledgments .....	XV

## Head

### 1 Embryology of the Head & Neck

Germ Layers & the Developing Embryo .....	2
Development of the Brain & Spinal Cord .....	4
Development & Derivatives of the Pharyngeal (Branchial) Arches .....	6
Development & Derivatives of the Pharyngeal Pouches, Membranes, & Clefts .....	8
Development of the Tongue & Thyroid Gland .....	10
Development of the Face .....	12
Development of the Palate .....	14

### 2 Cranial Bones

Development of the Cranial Bones .....	16
Skull: Lateral View .....	18
Skull: Anterior View .....	20
Skull: Posterior View .....	22
Calvaria .....	24
Skull Base: Exterior .....	26
Skull Base: Interior .....	28
Sphenoid Bone .....	30
Temporal Bone .....	32
Occipital Bone & Ethmoid Bone .....	34
Zygomatic (Malar) Bone & Nasal Bone .....	36
Maxilla & Hard Palate .....	38
Mandible & Hyoid Bone .....	40
Mandible: Age-related Changes & Mandibular Fractures .....	42
Neurovascular Pathways through the Skull Base .....	44
Muscles of the Head: Origins & Insertions .....	46
Radiographs of the Skull .....	48
Radiographs of the Sphenoid Bone .....	50

### 3 Vasculature & Lymphatics of the Head & Neck

Arteries of the Head & Neck: Overview & Subclavian Artery .....	52
External & Internal Carotid Arteries: Overview .....	54
External Carotid Artery: Anterior & Medial Branches .....	56
External Carotid Artery: Posterior Branches .....	58
External Carotid Artery: Terminal Branches (I) .....	60
External Carotid Artery: Terminal Branches (II) & Anastomoses .....	62
Internal Carotid Artery .....	64
Veins of the Head & Neck: Overview .....	66
Superficial Veins of the Head .....	68
Deep Veins of the Head .....	70
Lymphatics of the Head & Neck (I) .....	72
Lymphatics of the Head & Neck (II) .....	74
Radiographs of the Head & Neck .....	76

## 4 Neuroanatomy & Innervation of the Head & Neck

Organization of the Nervous System . . . . .	78
Spinal Cord: Overview . . . . .	80
Spinal Cord: Circuitry & Spinal Nerves . . . . .	82
Organization of the Brain & Cerebellum . . . . .	84
Telencephalon (I): Overview, Basal Ganglia, & Neocortex . . . . .	86
Telencephalon (II): Allocortex & Limbic System . . . . .	88
Diencephalon: Overview & Development . . . . .	90
Diencephalon: Thalamus & Hypothalamus . . . . .	92
Brainstem: Organization & External Structure . . . . .	94
Mesencephalon & Pons: Transverse Sections . . . . .	96
Medulla Oblongata: Transverse Sections . . . . .	98
Cerebrospinal Fluid (CSF) Spaces & Ventricles . . . . .	100
Arteries of the Brain . . . . .	102
Veins of the Brain: Superficial & Deep Veins . . . . .	104
Blood Vessels of the Brain: Cerebrovascular Disease . . . . .	106
Meninges . . . . .	108
Sensory Pathways (Excluding the Head) . . . . .	110
Sensory Pathways: Pain Pathways in the Head & the Central Analgesic System . . . . .	112
Motor Pathways . . . . .	114
Autonomic Nervous System (I): Overview . . . . .	116
Autonomic Nervous System (II): Connections . . . . .	118
Cranial Nerves: Overview . . . . .	120
Cranial Nerve Nuclei . . . . .	122
CN I & II: Olfactory & Optic Nerves . . . . .	124
CN III, IV, & VI: Oculomotor, Trochlear, & Abducent Nerves . . . . .	126
CN V: Trigeminal Nerve, Nuclei, & Divisions . . . . .	128
CN V <sub>1</sub> : Trigeminal Nerve, Ophthalmic Division . . . . .	130
CN V <sub>2</sub> : Trigeminal Nerve, Maxillary Division . . . . .	132
CN V <sub>3</sub> : Trigeminal Nerve, Mandibular Division . . . . .	134
CN VII: Facial Nerve, Nuclei & Internal Branches . . . . .	136
CN VII: Facial Nerve, External Branches & Ganglia . . . . .	138
CN VIII: Vestibulocochlear Nerve . . . . .	140
CN IX: Glossopharyngeal Nerve . . . . .	142
CN X: Vagus Nerve . . . . .	144
CN XI & XII: Accessory Spinal & Hypoglossal Nerves . . . . .	146
Radiographs of the Cranial Nerves Exiting the Brain (I) . . . . .	148
Radiographs of the Cranial Nerves Exiting the Brain (II) . . . . .	150

## Regions of the Head

### 5 Face & Scalp

Muscles of the Face . . . . .	154
Muscles of Facial Expression: Calvaria, Ear, & Eye . . . . .	156
Muscles of Facial Expression: Mouth . . . . .	158
Neurovascular Topography of the Anterior Face & Scalp: Superficial Layer . . . . .	160
Neurovascular Topography of the Lateral Head: Superficial Layer . . . . .	162
Neurovascular Topography of the Lateral Head: Intermediate & Deep Layers . . . . .	164

### 6 Temporal, Infratemporal, & Pterygopalatine Fossae

Temporal & Infratemporal Fossae: Contents . . . . .	166
Infratemporal Fossa: Contents . . . . .	168

Muscles of Mastication: Overview .....	170
Muscles of Mastication: Deep Muscles .....	172
Temporomandibular Joint (TMJ) .....	174
Temporomandibular Joint (TMJ): Biomechanics .....	176
Pterygopalatine Fossa: Overview .....	178
Topography of the Pterygopalatine Fossa .....	180
Radiographs of the Infratemporal Fossa .....	182

## 7 Nose & Nasal Cavity

Nose: Nasal Skeleton .....	184
Overview of the Nasal Cavity & Paranasal Sinuses .....	186
Nasal Cavity .....	188
Mucosa of the Nasal Cavity .....	190
Nose & Paranasal Sinuses: Histology & Clinical Anatomy .....	192
Olfactory System (Smell) .....	194
Radiographs of the Nasal Cavity .....	196
Radiographs of the Paranasal Sinuses .....	197

## 8 Oral Cavity & Pharynx

Oral Cavity: Overview .....	198
Vasculature of the Oral Cavity .....	200
Innervation of the Oral Cavity .....	202
Teeth in situ & Terminology .....	204
Structure of the Teeth & Periodontium .....	206
Maxillary Permanent Teeth .....	208
Mandibular Permanent Teeth .....	210
Deciduous Teeth .....	212
Radiographs of Teeth .....	214
Lingual Mucosa .....	216
Glossal Muscles .....	218
Neurovasculature of the Tongue .....	220
Gustatory Pathway .....	222
Floor of the Oral Cavity .....	224
Salivary Glands .....	226
Hard & Soft Palates .....	228
Pharynx: Divisions & Contents .....	230
Muscles of the Pharynx (I) .....	232
Muscles of the Pharynx (II) .....	234
Muscles of the Pharynx (III) & Innervation .....	236
Neurovascular Topography of the Pharynx .....	238
Potential Tissue Spaces in the Head & Spread of Dental Infections .....	240

## 9 Orbit & Eye

Bones of the Orbit .....	242
Communications of the Orbit .....	244
Extraocular Muscles .....	246
Innervation of the Extraocular Muscles (CN III, IV, & VI) .....	248
Neurovasculature of the Orbit .....	250
Topography of the Orbit (I) .....	252
Topography of the Orbit (II) .....	254
Lacrimal Apparatus .....	256
Eyeball .....	258
Eye: Blood Supply .....	260

Eye: Lens & Cornea . . . . .	262
Eye: Iris & Ocular Chambers . . . . .	264
Eye: Retina . . . . .	266
Visual System (I): Overview & Geniculate Part . . . . .	268
Visual System (II): Lesions & Nongeniculate Part . . . . .	270
Visual System (III): Reflexes . . . . .	272
Visual System (IV): Coordination of Eye Movement . . . . .	274
Radiographs of the Orbit . . . . .	276

## 10 Ear

Overview & External Ear (I) . . . . .	278
External Ear (II): Auricle . . . . .	280
Middle Ear (I): Tympanic Cavity & Pharyngotympanic Tube . . . . .	282
Middle Ear (II): Auditory Ossicles & Tympanic Cavity . . . . .	284
Inner Ear (I): Overview & Innervation (CN VIII) . . . . .	286
Arteries & Veins of the Middle & Inner Ear . . . . .	288
Inner Ear (II): Auditory Apparatus . . . . .	290
Auditory Pathway . . . . .	292
Inner Ear (III): Vestibular Apparatus . . . . .	294
Vestibular Pathway . . . . .	296
Radiographs of the Ear . . . . .	298

## Neck

### 11 Bones, Ligaments, & Muscles of the Neck

Vertebral Column & Vertebrae . . . . .	302
Cervical Spine . . . . .	304
Joints of the Cervical Spine . . . . .	306
Ligaments of the Vertebral Column . . . . .	308
Ligaments of the Cervical Spine . . . . .	310
Ligaments of the Craniovertebral Joints . . . . .	312
Muscles of the Neck: Overview . . . . .	314
Muscles of the Neck & Back (I) . . . . .	316
Muscles of the Neck & Back (II) . . . . .	318
Muscles of the Posterior Neck . . . . .	320
Intrinsic Back Muscles (I): Erector Spinae & Interspinales . . . . .	322
Intrinsic Back Muscles (II) . . . . .	324
Intrinsic Back Muscles (III): Short Nuchal & Craniovertebral Joint Muscles . . . . .	326
Prevertebral & Scalene Muscles . . . . .	328
Suprahyoid & Infrahyoid Muscles . . . . .	330
Radiographs of Bones & Muscles of the Neck . . . . .	332

### 12 Neurovascular Topography of the Neck

Arteries & Veins of the Neck . . . . .	334
Cervical Plexus . . . . .	336
Cervical Regions (Triangles) . . . . .	338
Cervical Fasciae . . . . .	340
Anterior Neck . . . . .	342
Root of the Neck . . . . .	344
Lateral Neck . . . . .	346
Deep Lateral Neck . . . . .	348

Posterior Neck . . . . .	350
Peripharyngeal Space (I) . . . . .	352
Peripharyngeal Space (II) . . . . .	354
Radiographs of the Neurovascular Topography of the Neck . . . . .	356

### 13 Larynx & Thyroid Gland

Larynx . . . . .	358
Laryngeal Muscles. . . . .	360
Larynx: Neurovasculature . . . . .	362
Larynx: Topography . . . . .	364
Endotracheal Intubation. . . . .	366
Thyroid & Parathyroid Glands. . . . .	368
Radiographs of the Larynx . . . . .	370

## Sectional Anatomy

### 14 Sectional Anatomy of the Head & Neck

Coronal Sections of the Head (I): Anterior . . . . .	374
Coronal Sections of the Head (II): Posterior . . . . .	376
Coronal MRIs of the Head . . . . .	378
Coronal MRIs of the Neck (I): Anterior. . . . .	380
Coronal MRIs of the Neck (II): Middle . . . . .	382
Coronal MRIs of the Neck (III): Posterior . . . . .	384
Transverse Sections of the Head (I): Cranial . . . . .	386
Transverse Sections of the Head (II) . . . . .	388
Transverse Sections of the Head (III): Caudal . . . . .	390
Transverse Sections of the Neck (I): Cranial . . . . .	392
Transverse Sections of the Neck (II): Caudal . . . . .	394
Transverse MRIs of the Head . . . . .	396
Transverse MRIs of the Oral Cavity . . . . .	398
Transverse MRIs of the Neck . . . . .	400
Sagittal Sections of the Head (I): Medial . . . . .	402
Sagittal Sections of the Head (II): Lateral . . . . .	404
Sagittal MRIs of the Head. . . . .	406
Sagittal MRIs of the Neck. . . . .	408

## Rest of Body Anatomy

### 15 Rest of Body Anatomy

Upper Limb	
Clavicle & Scapula . . . . .	412
Humerus & Glenohumeral Joint . . . . .	414
Bones of Forearm, Wrist, & Hand . . . . .	416
Muscles of the Shoulder (I) . . . . .	418
Muscles of the Shoulder (II) & Arm . . . . .	420
Muscles of the Forearm . . . . .	422
Muscles of the Wrist & Hand . . . . .	424
Arteries & Veins of the Upper Limb . . . . .	426
Brachial Plexus . . . . .	428

Thorax	
Thoracic Skeleton	430
Muscles & Neurovascular Topography of the Thoracic Wall	432
Female Breast	434
Diaphragm	436
Neurovasculature of the Diaphragm	438
Divisions of the Thoracic Cavity & Lymphatics	440
Thoracic Vasculature	442
Nerves of the Thoracic Cavity	444
Mediastinum: Overview	446
Mediastinum: Structures	448
Heart: Surfaces & Chambers	450
Heart: Valves, Arteries, & Veins	452
Heart: Conduction & Innervation	454
Pre- & Postnatal Circulation	456
Esophagus	458
Pleura	460
Lungs in situ	462
Pulmonary Arteries & Veins	464
Abdomen	
Surface Anatomy & Muscles of the Abdominal Wall	466
Arteries of the Abdominal Wall & Abdomen	468
Divisions of the Abdominopelvic Cavity	470
Peritoneal Cavity, Greater Sac, & Mesenteries (I)	472
Stomach & Omental Bursa	474
Mesenteries (II) & Bowel	476
Liver, Gallbladder, & Biliary Tract	478
Abdominal Aorta & Celiac Trunk	480
Superior & Inferior Mesenteric Arteries	482
Veins of the Abdomen	484
Inferior Vena Cava & Inferior Mesenteric Veins	486
Autonomic Plexuses & Sectional Anatomy of the Abdomen	488
Pelvis	
Pelvic Girdle & Ligaments of the Pelvis	490
Contents of the Pelvis	492
Arteries & Veins of the Pelvis	494

## Appendices

Appendix A	
Anatomy of Local Anesthesia for Dentistry	498
Appendix B	
Factual Questions & Answer Explanations	516
Appendix C	
Clinical Questions & Answer Explanations	537

Index	553
-------	-----

# Preface

The third edition of *Anatomy for Dental Medicine* keeps the key features of the first and second editions:

- A user-friendly format in which each two-page spread is a self-contained guide to a specific topic.
- An intuitive approach to each region, in which bones and joints are discussed first, followed by muscles, vasculature, and nerves, before showing an integrated neurovasculature topography.
- Detailed artwork supplemented with descriptive captions, simplified schematics, and tables of key information.
- Chapter dedicated to sectional anatomy, comparing such images to clinical imagery, to demonstrate how students will see anatomical structures in a clinical setting.
- Systemic anatomy at the start of the book, followed by a regional approach that allows this atlas to be used in conjunction with many lecture- and dissection-based courses.
- Information on embryology, histology, neuroanatomy, and anatomy of the body below the head, which allows

students to integrate anatomy with different topics and makes this atlas a good companion for combined courses, as well as courses that only cover anatomy of the head and neck.

- An appendix that explains the anatomical basis of local anesthesia techniques used in dentistry.
- Two appendices with practice questions and explanations.

In preparing the third edition, we included additional radiology images to enhance the clinical relevance of the anatomy depicted in the artwork. We also added discussions of several structures that are commonly used as landmarks, both in learning the anatomy as a student and in the clinical setting. We reorganized the neuroanatomy sections to be in a more logical progression. And finally, we added additional practice questions, including some in the style of the Integrated National Board Dental Examination (INBDE).

# Acknowledgments

First, we would like to thank our New York University dentistry students for their feedback on the second edition. We would also like to thank our colleagues at NYU for their assistance with this third edition (as well as previous editions): Dr. Richard Cotty, Dr. Johanna Warshaw, Dr. Jessica Manser, Dr. Julie O'Meara, Dr. Elena Cunningham, and Professor Joshua Johnson. Special thanks are due to Dr. Louis Terracio and Dr. Nicola Partridge for their support of all things related to anatomical education at NYU Dentistry.

For their invaluable input and advise in preparing the third edition, thanks to:

- Michelle Singleton, PhD, Professor of Anatomy, College of Graduate Studies, Midwestern University, Downers Grove, Illinois
- Earlanda L. Williams, PhD, University of the Incarnate Word, School of Osteopathic Medicine, San Antonio, Texas
- Alison F. Doubleday, PhD, Associate Professor, Department of Oral Medicine and Diagnostic Sciences, University of Illinois at Chicago, College of Dentistry, Chicago, Illinois
- Jessica M. Manser, PhD, Adjunct Assistant Professor, Department of Basic Science and Craniofacial Biology, New York University, College of Dentistry, New York, New York
- Claire A. Kirchhoff, PhD, Department of Biomedical Sciences, Marquette University, Milwaukee, Wisconsin
- Anita Joy-Thomas, BDS, PhD, Professor, Anatomical Sciences, Department of Diagnostic and Biomedical Sciences, University of Texas Health Science Center at Houston, School of Dentistry, Houston, Texas

We thank those who helped shape the second edition of this atlas: Dr. Roger A. Dashner, Clinical Anatomist and CEO, Advanced Anatomical Services, Columbus, Ohio; Dr. Dorothy Burk, Associate Professor of Biomedical Sciences, University of the Pacific Arthur A. Dugoni School of Dentistry, San Francisco, California; Douglas Gould, PhD, Professor, Oakland University William Beaumont School of Medicine, Rochester, Michigan; Dr. Stanley P. Freeman, DDS, FACD, FICD, Course Director and Professor of Dental Anatomy, Columbia School of Dentistry, New York; Dr. Bob Hutchins, Professor of Biomedical Sciences, TX A&M University, Baylor College of Dentistry, Dallas, TX (recently retired); Dr. Geoffroy Noel, Assistant Professor and Director of Division of Anatomical Sciences, McGill University, Montreal, Quebec, Canada; Justin Gorgi PhD, Associate Professor, Midwestern University, Glendale, Arizona; Michelle Singleton, PhD, Professor of Anatomy, Chicago College of Osteopathic Medicine, Midwestern University, Downers Grove, Illinois; Dr. Nicole Herring, Assistant Professor of Anatomical Sciences and Neurobiology, University of Louisville, Louisville, Kentucky; Dr. Rita Hardiman, Lecturer in Oro-facial and Head and Neck

Anatomy, Melbourne Dental School, University of Melbourne, Parkville, Australia; Brian R. MacPherson, PhD, Professor and Vice-Chair, Department of Anatomy and Neurobiology, University of Kentucky College of Medicine, Lexington, Kentucky; Henry Edinger, PhD, Director of Educational Programs, Department of Pharmacology & Physiology, Rutgers-New Jersey Medical School, Newark, New Jersey.

For the clinical vignette-style questions and the factual-type questions, respectively, thanks to:

- Dr. Lawrence C. Zoller, Professor of Biomedical Sciences, UNLV School of Dental Medicine, Las Vegas, Nevada
- Frank J. Daly, PhD, Associate Professor of Anatomy, University of New England College of Osteopathic Medicine, Biddeford, Maine

For their contribution to photographic coverage of the anatomy of dental local anesthesia, thanks to:

- Dr. Stanley P. Freeman, Dr. Brian S. Duchan, Alison Smith, Jazmin Smith, and Bridget Bieler of Westport Dental Associates.

Thank you to our colleagues at New York University who contributed to the second edition: Dr. Jean-Pierre Saint-Jeannet for his expert opinions related to the expanded neuroanatomy coverage in this edition; Dr. Kenneth Allen for his review of the coverage of the anatomy of local anesthesia; and Dr. Kenneth Fleisher for his assistance with the photographic coverage of the anatomy of dental local anesthesia.

We thank those who helped shape the original edition of this atlas: Susana Tejada, class of 2010, Boston University School of Dental Medicine; Dr. Norman F. Capra, Department of Neural and Pain Sciences, University of Maryland Dental School, Baltimore, Maryland; Dr. Bob Hutchins, Associate Professor, Department of Biomedical Sciences, Baylor College of Dentistry, Dallas, Texas; Dr. Brian R. MacPherson, Professor and Vice-Chair, Department of Anatomy and Neurobiology, University of Kentucky, Lexington, Kentucky; and Dr. Nicholas Peter Piesco, Associate Professor, Department of Oral Medicine, University of Pittsburgh, Pittsburgh, Pennsylvania.

We would once again like to thank everyone at Thieme Publishers who so professionally facilitated the production of this atlas: Dr. Cathrin Weinstein, Bridget Queenan, Dr. Julie O'Meara, Elsie Starbecker, Anne T. Vinnicombe, Huvie Weinreich, Dr. Barbara Chernow, Sarah Landis, and Delia DeTurris.

Finally, we thank the authors of the original Prometheus text, Michael Schuenke, MD, PhD, Erik Schulte, MD, and Udo Schumacher, MD, FRCPath, CBiol, FRSB, DSc, as well as the illustrators, Markus Voll and Karl Wesker.

# Head

## 1 Embryology of the Head & Neck

Germ Layers & the Developing Embryo	2
Development of the Brain & Spinal Cord	4
Development & Derivatives of the Pharyngeal (Branchial) Arches	6
Development & Derivatives of the Pharyngeal Pouches, Membranes, & Clefts	8
Development of the Tongue & Thyroid Gland	10
Development of the Face	12
Development of the Palate	14

## 2 Cranial Bones

Development of the Cranial Bones	16
Skull: Lateral View	18
Skull: Anterior View	20
Skull: Posterior View	22
Calvaria	24
Skull Base: Exterior	26
Skull Base: Interior	28
Sphenoid Bone	30
Temporal Bone	32
Occipital Bone & Ethmoid Bone	34
Zygomatic (Malar) Bone & Nasal Bone	36
Maxilla & Hard Palate	38
Mandible & Hyoid Bone	40
Mandible: Age-related Changes & Mandibular Fractures	42
Neurovascular Pathways through the Skull Base	44
Muscles of the Head: Origins & Insertions	46
Radiographs of the Skull	48
Radiographs of the Sphenoid Bone	50

## 3 Vasculature & Lymphatics of the Head & Neck

Arteries of the Head & Neck:	
Overview & Subclavian Artery	52
External & Internal Carotid Arteries: Overview	54
External Carotid Artery: Anterior & Medial Branches	56
External Carotid Artery: Posterior Branches	58
External Carotid Artery: Terminal Branches (I)	60
External Carotid Artery: Terminal Branches (II) & Anastomoses	62
Internal Carotid Artery	64
Veins of the Head & Neck: Overview	66
Superficial Veins of the Head	68
Deep Veins of the Head	70

Lymphatics of the Head & Neck (I)	72
Lymphatics of the Head & Neck (II)	74
Radiographs of the Head & Neck	76

## 4 Neuroanatomy & Innervation of the Head & Neck

Organization of the Nervous System	78
Spinal Cord: Overview	80
Spinal Cord: Circuitry & Spinal Nerves	82

# Germ Layers & the Developing Embryo

**Fig. 1.1 Embryonic development** (after Sadler)  
Age in postovulatory days.  
**A-C** Posterior (dorsal) view after removal of the amnion.  
**D-E** Schematic cross sections of the corresponding stages at the horizontal planes of section marked in **A** to **C**. Gastrulation occurs in week 3 of human embryonic development. It produces three germ layers in the embryonic disk: ectoderm (light grey), mesoderm (red), and endoderm (dark grey).  
**A, D** Day 19, the three layers are visible in the embryonic disk. The amnion forms the amniotic cavity dorsally, and the endoderm encloses

the yolk sac. The neural tube is developing in the area of the neural plate.  
**B, E** Day 20, the first somites have formed, and the neural groove is beginning to close to form the neural tube, with initial folding of the embryo.  
**C, F** Day 22, eight pairs of somites flank the partially closed neural tube, which has sunk below the ectoderm. The yolk sac elongates ventrally to form the gut tube and yolk sac. At the sites where the neural folds fuse to close the neural tube, cells form a bilateral neural crest that detaches from the surface and migrates into the mesoderm.

Table 1.1 Differentiation of germ layers			
Germ layer	Embryonic structure		Adult derivative
Ectoderm	Neural tube		Brain, retina, spinal cord
	Neural crest	Neural crest of the head	Sensory and parasympathetic ganglia; parafollicular cells; pigment cells; carotid body; cartilage, bone, dermis, subcutaneous tissue, and other connective tissues in the head; part of cardiac septum
		Neural crest of the trunk	Sensory, sympathetic, and parasympathetic ganglia; peripheral glia; pigment cells; adrenal medulla; intramural plexuses and enteric nervous system
	Surface ectoderm	Placodes	Anterior pituitary, cranial sensory ganglia, olfactory epithelium, inner ear, lens
			Epithelium of the oral cavity, salivary glands, nasal cavities, paranasal sinuses, lacrimal passages, external auditory canal, epidermis, hair, nails, cutaneous glands
Mesoderm	Paraxial	Somites	Dermis of skin (from dermatome), musculature (from myotome), vertebral column (from sclerotome)
	Axial	Notochord	Nucleus pulposus
		Prechordal mesoderm	Extraocular muscles
	Intermediate		Kidneys, gonads, renal and genital excretory ducts
	Lateral plates	Visceral (splanchnic)	Heart, blood vessels, smooth muscle, bowel wall, blood, adrenal cortex, visceral serosa
		Parietal (somatic)	Sternum, limbs without muscles (muscles develop from the myotomes), dermis and subcutaneous tissue of the anterolateral body wall, smooth muscle, connective tissue, parietal serosa
Endoderm	Intestinal tube		Epithelium of the bowel, respiratory tract, digestive glands, pharyngeal glands, pharyngotympanic (auditory) tube, tympanic cavity, urinary bladder, parathyroid glands, thyroid gland

**Fig. 1.2 Somatic muscle development**

Age in postovulatory days. Each somite divides into a dermatome (cutaneous), myotome (muscular), and sclerotome (vertebral) at around day 22 (see **Fig. 1.1**).

**A** Day 28, sclerotomes migrate to form the vertebral column around the notochord (primitive spinal cord).

**B** Day 30, all 34 or 35 somite pairs have formed. The neural tube differentiates into a primitive spinal cord. Motor and sensory neurons differentiate in the anterior and posterior horns of the spinal cord, respectively.

**C** By day 40, the posterior and anterior roots form the mixed spinal nerve. The posterior branch supplies the epiaxial muscles (future intrinsic back muscles); the anterior branch supplies the hypaxial muscles (anterior muscles, including all muscles except the intrinsic back muscles).

**D** Week 8, the epiaxial and hypaxial muscles have differentiated into the skeletal muscles of the trunk. Cells from the sclerotomes also migrate into the limbs. During this migration, the spinal nerves form the plexuses (cervical, branchial, and lumbosacral), which innervate the muscles of the neck, upper limb, and lower limb, respectively.

**Fig. 1.3 5-week-old embryo**

The human embryo at 5 weeks has a crown-rump length of approximately 5 to 7 mm. The umbilical cord, which attaches the embryo to the mother, is seen. The future cerebral hemispheres form along with the eye, ear, pharyngeal arches (which form a large portion of the structures of the head and neck), heart, neural tube, and limb buds.

## Development of the Brain & Spinal Cord

**Fig. 1.4 Development of the neural tube and neural crest** (after Wolpert)

The tissues of the nervous system originate embryonically from the posterior surface ectoderm. The notochord in the midline of the body induces the formation of the neural plate, which lies dorsal to the notochord, and of the neural crests, which are lateral to the notochord. With further development, the neural plate deepens at the center to form the neural groove, which is flanked on each side by the neural folds. Later the groove deepens and closes to form the neural tube, which sinks below the ectoderm. The neural tube is the structure from which the central nervous system (CNS) – the brain and spinal cord –

develops (further development of the spinal cord is shown in **Fig. 1.5**, further brain development in **Fig. 1.7**). Failure of the neural folds to fuse completely in the caudal region will leave an anomalous cleft in the vertebral column known as spina bifida. In the cranial region, this will lead to a defect known as anencephaly. The administration of folic acid to potential mothers around the time of conception can significantly reduce the incidence of spina bifida and other neural tube defects. Cells that migrate from the neural crest develop into various structures, including cells of the peripheral nervous system (PNS), such as Schwann cells, and the pseudounipolar cells of the spinal ganglion (see **Fig. 1.6**).

**Fig. 1.5 Differentiation of the neural tube in the spinal cord during development**

Cross-section, superior view.

**A** Early neural tube. **B** Intermediate Stage. **C** Adult spinal cord.

The neurons that form the basal plate are efferent (motor neurons), while the neurons that form the alar plate are afferent (sensory neurons). In the future thoracic, lumbar, and sacral spinal cord, there is another zone between them that gives rise to autonomic neurons. The roof plate and the floor plate do not form neurons.

**Fig. 1.6 Development of a peripheral nerve**

Afferent (sensory) axons (blue) and efferent (motor) axons (red) sprout from the neuronal cell bodies during early embryonic development.

**A** Primary afferent neurons develop in the spinal ganglion, and alpha motor neurons develop from the basal plate of the spinal cord.

**B** The interneurons (black), which functionally interconnect the afferent and efferent neurons, develop at a later stage.

**Fig. 1.7 Development of the brain**

**A** Embryo with the greatest length (GL) of 10 mm at the beginning of the 2nd month of development. Even at this stage, we can see the differentiation of the neural tube into segments that will generate various brain regions.

- Red: telencephalon (cerebrum)
- Yellow: diencephalon
- Dark blue: mesencephalon (midbrain)
- Light blue: cerebellum
- Gray: pons and medulla oblongata

**Note:** The telencephalon outgrows all of the other brain structures as development proceeds.

**B** Embryo with a GL of 27 mm near the end of the 2nd month of development (end of the embryonic period). The telencephalon and the diencephalon have enlarged. The olfactory bulb is developing from the telencephalon, and the primordium of the pituitary gland is developing from the diencephalon.

**C** Fetus with a GL of 53 mm in approximately the 3rd month of development. By this stage the telencephalon has begun to cover the other brain areas. The insula is still on the brain surface but will subsequently be covered by the hemispheres (compare with **D**).

**D** Fetus with GL of 27 cm (270 mm) in approximately the 7th month of development. The cerebrum (telencephalon) has begun to develop well-defined gyri and sulci.

**Table 1.2 Development of the brain**

Primary vesicle		Region		Structure
Neural tube	Prosencephalon (forebrain)	Telencephalon		Cerebral cortex, white matter, basal ganglia
		Diencephalon		Epithalamus (pineal gland), thalamus, subthalamus, hypothalamus
	Mesencephalon (midbrain)*			Tectum, tegmentum, cerebral peduncles
	Rhombencephalon (hindbrain)	Metencephalon	Cerebellum	Cerebellar cortex, nuclei, peduncles
			Pons*	Nuclei, fiber tracts
		Myelencephalon	Medulla oblongata*	Nuclei, fiber tracts

\*The mesencephalon, pons, and medulla oblongata are collectively known as the brainstem.

## Development & Derivatives of the Pharyngeal (Branchial) Arches

**Fig. 1.8** Head and neck region of a 5-week-old embryo, showing the pharyngeal (branchial) arches and clefts

Left lateral view. The pharyngeal arches are instrumental in the development of the face, neck, larynx, and pharynx. Development of the pharyngeal arches begins in the 4th week of embryonic life as cells migrate from the neural crest to the future head and neck region. Within 1 week, a series of four oblique ridges (first through sixth pharyngeal arches, with the fifth arch only rudimentary in humans and the sixth arch not visible on the surface) form that are located at the level of the cranial segment of the foregut and are separated externally by four deep grooves (pharyngeal clefts). The pharyngeal arches and clefts are prominent features of the embryo at this stage.

**Fig. 1.9** Cross section through an embryo at the level of the pharyngeal gut (after Drets)

Left superior oblique view. Due to the craniocaudal curvature of the embryo, the cross section passes through the pharyngeal arches and pharyngeal gut as well as the prosencephalon and spinal cord. The pharyngeal gut is bounded on both sides by the pharyngeal arches, which contain the mesodermal core. They are covered externally by ectoderm and internally by endoderm. Ectodermal pharyngeal clefts and endodermal pharyngeal pouches lie directly opposite one another. Because the embryo is curved craniocaudally, the pharyngeal gut and pharyngeal arches overlie the prominence of the rudimentary heart and liver.

**Fig. 1.10** Structure of the pharyngeal arches (after Sadler)

**A** Cross section through a pharyngeal arch and the neural tube, showing the pharyngeal arch cartilage and artery. **B** Oblique cross section through a pharyngeal arch and the neural tube, showing the pharyngeal arch nerves. **C** Blow up of section in **B**, showing the relationship of pharyngeal arch cartilage, artery, and nerve in the pharyngeal arches. The pharyngeal arches are covered externally by ectoderm (blue) and internally by endoderm (green). Each pharyngeal arch contains an arch artery, an arch nerve, and a cartilaginous skeletal element, all of which

are surrounded by mesenchyme and muscular tissue. The external grooves are called the pharyngeal clefts, and the internal grooves are called the pharyngeal pouches.

**Fig. 1.11 The arrangement and derivatives of the pharyngeal arches** (after Sadler and Drews)

- A** The pharyngeal arches with the associated pharyngeal arch nerves
- B** The mandibular nerve (CN V<sub>3</sub>), facial nerve (CN VII), glossopharyngeal nerve (CN IX), and vagus nerve (CN X) derived from the pharyngeal arch nerves
- C** Muscles derived from the pharyngeal arches
- D** Skeletal and ligamentous elements derived from the pharyngeal arches

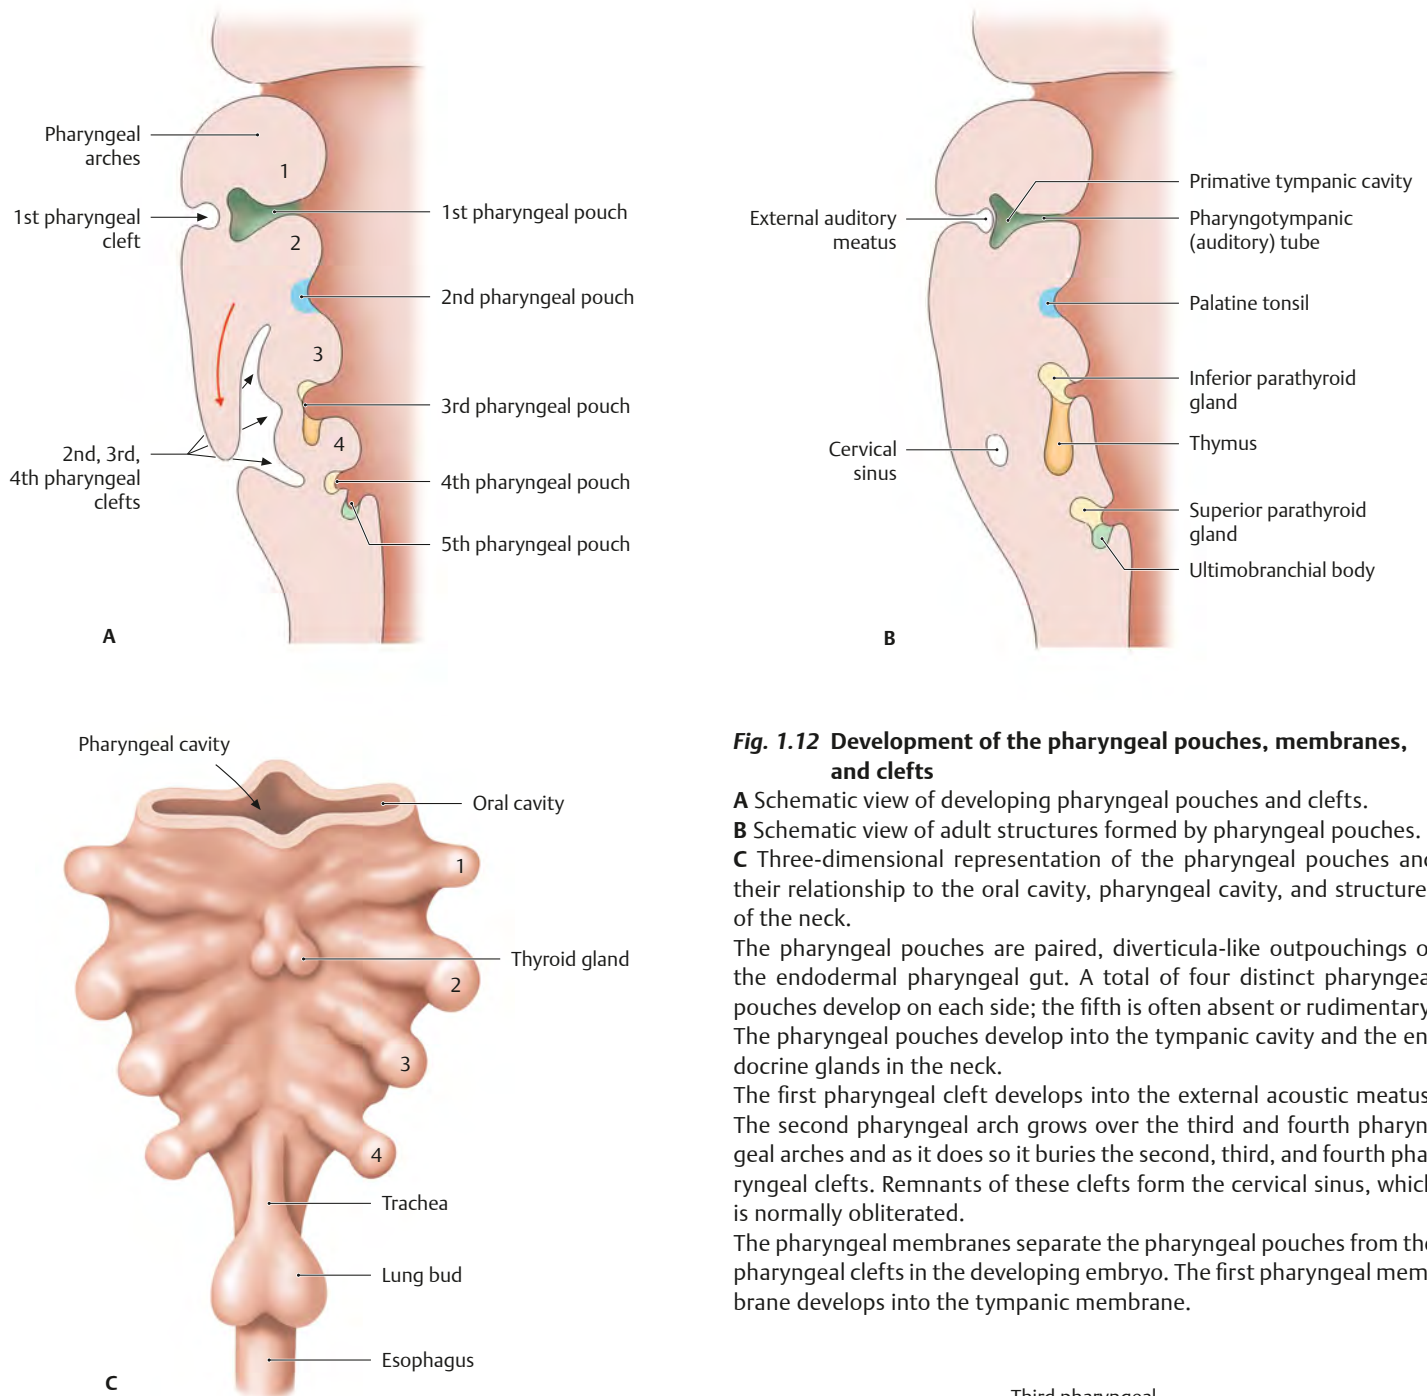

**Table 1.3 Derivatives of the pharyngeal arches**

Pharyngeal arch	Muscles*		Skeletal and ligamentous elements	Nerve accompanying arch
1	Muscles of mastication <ul style="list-style-type: none"> <li>• Temporalis</li> <li>• Masseter</li> <li>• Lateral pterygoid</li> <li>• Medial pterygoid</li> </ul> Mylohyoid Digastric, anterior belly Tensor tympani Tensor veli palatini		Maxilla Mandible Malleus and incus Meckel's cartilage Sphenomandibular ligament Anterior ligament of malleus	Mandibular n. (CN V <sub>3</sub> )
2	Muscles of facial expression Stylohyoid Digastric, posterior belly Stapedius		Stapes Styloid process, temporal bone Lesser horn, hyoid bone Upper part, hyoid bone Stylohyoid ligament	Facial n. (CN VII)
3	Stylopharyngeus		Greater horn, hyoid bone Lower part, hyoid bone	Glossopharyngeal n. (CN IX)

(CN X)

Abbreviation: CN, cranial nerve.

\*All branchial skeletal muscles

## Development & Derivatives of the Pharyngeal Pouches, Membranes, & Clefts

**Fig. 1.12 Development of the pharyngeal pouches, membranes, and clefts**

**A** Schematic view of developing pharyngeal pouches and clefts.

**B** Schematic view of adult structures formed by pharyngeal pouches.

**C** Three-dimensional representation of the pharyngeal pouches and their relationship to the oral cavity, pharyngeal cavity, and structures of the neck.

The pharyngeal pouches are paired, diverticula-like outpouchings of the endodermal pharyngeal gut. A total of four distinct pharyngeal pouches develop on each side; the fifth is often absent or rudimentary. The pharyngeal pouches develop into the tympanic cavity and the endocrine glands in the neck.

The first pharyngeal cleft develops into the external acoustic meatus. The second pharyngeal arch grows over the third and fourth pharyngeal arches and as it does so it buries the second, third, and fourth pharyngeal clefts. Remnants of these clefts form the cervical sinus, which is normally obliterated.

The pharyngeal membranes separate the pharyngeal pouches from the pharyngeal clefts in the developing embryo. The first pharyngeal membrane develops into the tympanic membrane.

**Fig. 1.13 Pharyngeal pouches and the aortic arches** (after Sadler)

The aortic arches (pharyngeal arch arteries) arise from the paired embryonic anterior aorta and run between the pharyngeal pouches. They open posteriorly into the posterior aorta, which is also paired. The definitive aortic arch develops from the fourth aortic arch on the left side. Note: The pouch protruding from the roof of the oral cavity is called Rathke's pouch (precursor of the anterior pituitary). Note also the lung bud extending anteriorly from the pharyngeal gut, and the primordial (anlage) of the thyroid gland.

**Table 1.4 Derivatives of the pharyngeal pouches**

Pouch	Germ layer	Embryonic structure	Adult structure
1	Endoderm	Tubotympanic recess	Epithelium of the pharyngotympanic (auditory) tube Tympanic cavity
2		Primitive palatine tonsils	Tonsillar fossa Epithelium of the palatine tonsil
3		Divides into a posterior and an anterior part at its distal end	Inferior parathyroid gland (from posterior part) Thymus (from anterior part)
4		Divides into a posterior and an anterior part at its distal end	Superior parathyroid gland (from posterior part) Ultimobranchial body (from anterior part). This is later incorporated in thyroid gland and gives rise to the parafollicular or C cells, which secrete calcitonin.

**Table 1.5 Derivative of the pharyngeal membranes**

Membranes	Germ layers	Adult structure
1	Composed externally of ectoderm and internally of endoderm. The intervening core consists of mesoderm and neural crest cells.	Tympanic membrane
2 to 4		The 2nd to 4th membranes disappear when the 2nd arch grows over the cleft

**Table 1.6 Derivatives of the pharyngeal clefts**

Cleft	Germ layer	Adult structure
1	Ectoderm	External acoustic meatus
2 to 4		Cervical sinus, which is rapidly obliterated by the 2nd pharyngeal arch, which grows over clefts 2 to 4

**Treacher Collins syndrome** is a rare autosomal dominant craniofacial defect involving the structures derived from the first pharyngeal arch. It is characterized by malar hypoplasia (underdevelopment or incomplete development of the cheek), mandibular hypoplasia, downslanting eyes, eyelid coloboma (notching of the lower eyelids), and malformed external ears. It may also be associated with cleft palate, hearing loss (due to defects in the ossicles), vision loss, and difficulty breathing (dyspnea). Treatment will depend on the severity of the defects but will involve a multidisciplinary team of clinicians.

**Pierre-Robin syndrome** is characterized by an abnormally small mandible (micrognathia). As a result, the tongue musculature is unsupported by the mandible, allowing it to displace posteriorly, partially obstructing the airway, resulting in dyspnea (shortness of breath). This posterior displacement of the tongue (glossoptosis) is also responsible for cleft palate because it prevents the palatal shelves from fusing (see **Figs. 1.21** and **1.22**). Initial treatment involves surgery to repair the cleft palate to improve feeding and speech development.

## Development of the Tongue & Thyroid Gland

**Fig. 1.14 Development of the tongue**

**A** Early tongue development, around week 4. **B** Late tongue development, around week 8.

The tongue develops within the pharynx. While the musculature of the tongue is derived from somites, the tongue develops from the four pharyngeal (lingual) swellings. Three swellings are associated with the 1st arch and one, with the 3rd, 4th, and 6th arches. The two lateral and one midline swelling (the tuberculum impar) from the 1st pharyngeal arch contribute to the development of the anterior two thirds of the tongue. The single midline swelling (the hypobranchial eminence [copula]) from the 3rd, 4th, and 6th arches contributes to the development of the posterior one third of the tongue. A U-shaped sulcus develops around the tongue allowing it to move freely, except in one area, which is the lingual frenulum, which anchors the tongue to the floor of the oral cavity.

The lingual mucosa derived from the 1st arch swelling that covers the anterior two thirds of the tongue is innervated by the mandibular division of the trigeminal nerve (GSA) and the chorda tympani branch of

the facial nerve (SVA); the lingual mucosa derived from the 3rd, 4th, and 6th arch swellings receives sensory innervation from both CN IX (glossopharyngeal nerve) and CN X (vagus nerve).

The V-shaped terminal sulcus (sulcus terminalis) separates the anterior two thirds of the tongue from the posterior one third. Located at the vertex of the terminal sulcus, between the tuberculum impar and the hypobranchial eminence, the foramen cecum marks the site of exit for the thyroid gland from the floor of the inside of the pharynx to an extrapharyngeal location.

Ankyloglossia (tongue-tie) is a congenital anomaly in which the lingual frenulum is unusually short or thick, thereby tethering the ventral surface of the tip of the tongue to the floor of the mouth. Clinical features include restricted elevation, protrusion, and side-to-side movement of the tongue, and demonstration of a heart-shaped tongue on protrusion. It may be noticed as difficulty feeding in infants. Treatment, when required, involves a frenectomy, where the frenulum is incised, releasing the tongue.

**Table 1.7 Derivation of the tongue**

Pharyngeal arch	Embryonic structure(s)	Adult structure	Innervation
1	Two lateral lingual swellings Tuberculum impar	Anterior two thirds of the tongue	GSA: lingual branch of the mandibular division of the trigeminal n. (CN V <sub>3</sub> )
2	Is obliterated by the 3rd arch and therefore does not contribute to the adult tongue Hypobranchial eminence (minor involvement)	-	SVA: chorda tympani branch of the facial n. (CN VII) (it carries sensation from the anterior 2/3 of the tongue)
3	Hypobranchial eminence	Posterior one third of the tongue	GSA: glossopharyngeal n. (CN IX) SVA: glossopharyngeal n. (CN IX)
4	Hypobranchial eminence Epiglottic swelling Arytenoid swelling Laryngotracheal groove	Root of the tongue	GSA: internal laryngeal branch of the vagus n. (CN X) SVA: internal laryngeal branch of the vagus n. (CN X)

Abbreviations: GSA, general somatic afferent; SVA, special visceral afferent.

**Table 1.8 Derivation of the skeletal muscles of the tongue**

Muscle origin	Muscles	Cranial nerves
Somites (from myotomes)	Intrinsic muscles of the tongue Extrinsic muscles of the tongue (genioglossus, styloglossus, and hyoglossus; <b>not</b> palatoglossus)	Hypoglossal n. (CN XII)

**Fig. 1.15 Migration of the pharyngeal arch tissues** (after Sadler)

Anterior view. During embryonic development, the epithelium from which the thyroid gland forms migrates from its site of origin on the basal midline of the tongue to the level of the first tracheal cartilage, where the thyroid gland is located in postnatal life. As the thyroid tissue buds off from the tongue base, it leaves a vestigial depression on the dorsum of the tongue, the foramen cecum. The parathyroid glands are derived from the 4th pharyngeal pouch (superior pair) or the 3rd pharyngeal pouch (inferior pair), which also gives rise to the thymus. The ultimobranchial body, whose cells migrate into the thyroid gland to form the calcitonin-producing C cells, or parafollicular cells, is derived from the 5th pharyngeal pouch. The external auditory meatus is derived from the 1st pharyngeal cleft, the tympanic cavity and pharyngotympanic tube from the 1st pharyngeal pouch, and the palatine tonsil from the 2nd pharyngeal pouch.

Ectopic thyroid is a rare condition in which the entire thyroid gland or thyroid tissues are not found in their normal position in the neck, i.e., inferolateral to the thyroid cartilage. Dentists may encounter this as a firm midline mass, which may appear as light pink to bright red, and may be regular or irregular on the dorsal tongue, just posterior to the foramen cecum (the embryonic origin of the thyroid gland). This is known as a lingual thyroid and represents approximately 90% of ectopic thyroid cases. Symptoms of lingual thyroid may include cough, pain, difficulty swallowing (dysphagia), difficulty speaking (dysphonia), and difficulty breathing (dyspnea).

**Fig. 1.16 Location of cysts and fistulas in the neck**

**A** Median cysts. **B** Median fistulas. **C** Lateral fistulas and cysts.

**A, B Median cysts and fistulas in the neck** are remnants of the thyroglossal duct. Failure of this duct to regress completely may lead to the formation of a mucus-filled cavity (cyst), which presents clinically as a palpable, fluctuant, midline swelling in the neck at around the level of the hyoid bone. It is seen to move upward on swallowing or protrusion of the tongue due to the connection of the tongue with the duct. Symptoms may include dyspnea (difficulty breathing), dysphagia (difficulty swallowing), and pain (only if the cyst becomes infected).

**C Lateral cysts and fistulas in the neck** are anomalous remnants of the ductal portions of the cervical sinus, which forms as a result of tissue migrations during embryonic development.

If epithelium-lined remnants persist, neck cysts (right) or fistulas (an abnormal communication between structures; left) may appear in postnatal life. A complete fistula opens into the pharynx and onto the surface of the skin, whereas an incomplete (blind) fistula is open at one end only. The external orifice of a lateral cervical fistula is typically located at the anterior border of the sternocleidomastoid muscle.

# Development of the Face

**Fig. 1.17 Development of the face** (after Sadler)

**A** Anterior view at 24 days. The surface ectoderm of the 1st pharyngeal arch invaginates to form the *stomodeum*, which is a depression between the forebrain and the pericardium in the embryo. It is the precursor of the mouth, oral cavity, and the anterior pituitary gland. At this stage, the stomodeum is separated from the primitive pharynx by the buccopharyngeal (oropharyngeal) membrane. This membrane later breaks down and the stomodeum become continuous with the pharynx.

The stomodeum is surrounded by five neural-crest-cell-derived mesenchymal swellings, known as *prominences*, which contribute to the development of the face.

**B** Anterior view at 5 weeks. Nasal placodes, ectodermal thickenings, form on each side of the frontonasal prominence. Invagination of the nasal placodes into the frontonasal prominence leads to the formation of the lateral and medial nasal prominences. The placodes now lie in the floor of a depression known as the *nasal pit*. The maxillary prominences continue to increase in size and merge laterally with the mandibular prominences to form the cheek. Medially, the maxillary prominences compress the medial nasal prominences toward the midline. A furrow (the nasooptic furrow) separates the nasal processes from the maxillary process. Ectoderm from the floor of the nasolacrimal groove (nasooptic furrow) will give rise to the nasolacrimal duct that connects the orbit with the nasal cavity; the two prominences will join to close the groove and create the nasolacrimal canal.

**C** Anterior view at 6 weeks. The medial nasal swellings enlarge, grow medially, and merge with each other to form the intermaxillary segment.

**D** Anterior view at 7 weeks. The medial nasal processes have fused with each other along the midline and with the maxillary processes and their lateral margins.

**E** Anterior view at 10 weeks. Cell migration is complete.

Table 1.9 Prominences contributing to facial structures	
Prominence	Facial structure
Frontonasal prominence*	Forehead, nose, medial and lateral nasal prominences
Maxillary prominences	Cheeks, lateral parts of the upper lip
Medial nasal prominences	Philtrum of the upper lip, crest and tip of nose
Lateral nasal prominences	Alae of nose
Mandibular prominences	Lower lip
*The frontonasal prominence is a single unpaired structure; all other prominences listed are paired.	

**Fig. 1.18 Development of the nasal cavity**

Sagittal section of embryo. At week 6, the primitive nasal cavity is separated from the oral cavity by the oronasal membrane (A), which then breaks down (B), leaving the nasal and oral cavities in open connection by week 7 (C). In week 9, the nasal cavity and oral cavity are in their definitive arrangement (D), separated by the primary and secondary palate with choanae at their junction in the pharynx. The lateral walls of

the nasal cavity develop the superior, middle, and inferior conchae. The ectodermal epithelium in the roof of the nasal cavity becomes the specialized olfactory epithelium. The olfactory cells within the olfactory epithelium give rise to the olfactory nerve fibers (CN I) that grow into the olfactory bulb. The nasal septum (not shown) develops as a down-growth of the merged medial nasal prominences. It fuses with the palatine process by weeks 9 to 12.

**Fig. 1.19 Development of the eyes and ears**

At about 22 days, the eyes and ears begin to develop. The eyes develop laterally in the embryo but during growth move medially to occupy their familiar position on the face. The auricle of the ear is formed from six swellings, known as *auricular hillocks*, from the first and second pharyngeal pouches. The germ layers that contribute to the eyes and ears are listed in Table 1.10.

**Table 1.10 Derivation of the structures of the eye and ear**

Germ layer	Structure	
Eye		
Surface ectoderm	Corneal and conjunctival epithelium, lens, lacrimal glands, tarsal glands	
Neural crest cell ectoderm (neuroectoderm)	Retina, optic nerve (CN II), iris	
Mesenchyme	Corneal stroma, sclera, choroid, iris, parts of vitreous, ciliary muscle, muscles lining the anterior chamber	
Ear		
Ectoderm	Otic placode	Vestibulocochlear organ
	1st pharyngeal cleft	External acoustic meatus
Mesoderm	Cartilaginous otic capsule	Bony labryrinth
	Auricular hillocks	Auricle
Endoderm	1st pharyngeal pouch	Middle ear and auditory tube

## Development of the Palate

**Fig. 1.20** Palate formation, 7- to 8-week-old embryo

Inferior view. Before the palate has formed, the oral cavity is open to the nasal cavity. The nasal septum can be seen as well as the oronasal membrane, which will ultimately form the choana. Development of the palate begins during week 5, but fusion of its parts is not complete until week 12. The most critical period for palate development is between the end of week 6 and the beginning of week 9. The palate forms from two major parts, the primary and secondary palates. The primary palate is derived from the wedge-shaped intermaxillary segment, which is formed by the merging of the two medial nasal prominences. The secondary palate is derived from two shelf-like outgrowths of the maxillary prominence, which, at this stage, are directed downward beside the tongue (removed).

**Fig. 1.21** Elevation of the palatine shelves

The palatine shelves, which form the secondary palate, are seen at around 6 weeks and are directed obliquely downward on each side of the tongue. At around 7 weeks, the palatine shelves ascend to a horizontal position above the tongue and fuse.

**Fig. 1.22** Fusion and merging of the palatine shelves

Fusion of the palate begins at around 9 weeks and is completed posteriorly by week 12. **(A)** The primary palate and both halves of the secondary palate migrate toward each other as indicated by the arrows. **(B)** They contact and fuse at a point (marked by the incisive foramen)

and merge anteriorly and posteriorly, as shown in **(C)** and **(D)**. The primary and secondary palates ossify, forming the hard palate. The posterior portions of the palatine shelves do not become ossified but extend beyond the nasal septum to form the soft palate and uvula.

**Fig. 1.23 Formation of facial clefts** (after Sadler)

Inferior view.

Clefts (fissures or openings) can involve the lips and/or the palate. Clefts are classified as isolated (cleft lip or cleft palate), unilateral or bilateral, and as complete (when they extend to the nose) or incomplete (if they do not extend to the nose).

**A Normal lips and palate**, in which the maxillary prominences and medial nasal prominences have merged to form the upper lip and primary palate. The primary palate has also fused with the palatine processes of the maxillary prominences (secondary palate) to form the complete, unified, hard palate. The posterior portion of the secondary palate is unossified and forms the soft palate and uvula.

**B Unilateral, complete cleft lip** results from failure of fusion of the maxillary prominence with the medial nasal prominence on the affected side.

**C Unilateral, complete cleft lip, alveolus, and primary palate** (part of palate anterior to the incisive foramen) results from failure of fusion

of the maxillary prominence with the medial nasal prominence on the affected side.

**D Bilateral, complete cleft lip, alveolus, and primary palate** result from failure of the maxillary prominences to fuse with the medial nasal prominences on both sides.

**E Cleft of secondary palate** (part of palate posterior to the incisive foramen) results from incomplete fusion of the two lateral palatine processes.

**F Unilateral, complete cleft lip and complete cleft palate** (involving both primary and secondary palate) result from failure of fusion of the maxillary prominence with the medial nasal prominence and failure of fusion of the two lateral palatine processes on the affected side.

Cleft lip and palate can cause difficulty in eating and speaking, and result in failure to thrive in infants. Treatment by a multidisciplinary team of healthcare professionals principally involves corrective surgery, which is usually performed between 6 and 12 months of age, often followed by surgical revisions, speech therapy, and orthodontic therapy.

# Development of the Cranial Bones

**Fig. 2.1 Bones of the skull**  
Left lateral view. The skull forms a bony capsule that encloses the brain and viscera of the head. The bones of the skull are divided into two parts. The viscerocranium (orange), the facial skeleton, is formed primarily from the pharyngeal (branchial) arches (see pp. 6 and 7). The neurocranium (gray), the cranial vault, is the bony capsule enclosing the brain. It is divided into two parts based on ossification (see **Fig. 2.2**). The *cartilaginous* neurocranium undergoes endochondral ossification to form the base of the skull. The *membranous* neurocranium undergoes intramembranous ossification.

**Fig. 2.2 Ossification of the cranial bones**  
Left lateral view. The bones of the skull develop either directly or indirectly from mesenchymal connective tissue. The bones of the *desmocranium* (gray) develop directly via intramembranous ossification of mesenchymal connective tissue. The bones of the *chondrocranium* (blue) develop indirectly via endochondral ossification of hyaline cartilage. *Note:* The skull base is formed exclusively by the chondrocranium. Elements formed via intramembranous and endochondral ossification may fuse to form a single bone (e.g., the elements of the occipital, temporal, and sphenoid bones contributing to the skull base are cartilaginous, while the rest of the bone is membranous).

**Fig. 2.3 Cranial sutures (craniosynostoses) and fontanelles**  
**A** Left lateral view of neonatal skull.  
**B** Superior view of neonatal skull.  
The flat cranial bones grow as the brain expands; thus the sutures between them remain open after birth. In the neonate, there are six areas

(fontanelles) between the still-growing cranial bones that are occupied by unossified fibrous membrane. The posterior fontanelle provides a reference point for describing the position of the fetal head during childbirth. The anterior fontanelle provides access for drawing cerebrospinal fluid (CSF) samples in infants (e.g., in suspected meningitis).

Table 2.1 Closure of sutures and fontanelles			
Fontanelle	Age at closure	Suture	Age at ossification
1 Posterior fontanelle	2–3 months (lambda)	Frontal suture	Childhood
2 Sphenoid (anterolateral) fontanelles	6 months (pterion)	Sagittal suture	20–30 years old
2 Mastoid (posterolateral) fontanelles	18 months (asterion)	Coronal suture	30–40 years old
1 Anterior fontanelle	36 months (bregma)	Lambdoid suture	40–50 years old

Table 2.2 Development of the skull

Bone	Ossification	Arch	Embryological tissue
<i>Viscerocranium</i>			
Maxilla (premaxilla)	I	Frontonasal process	Neural crest
Nasal bone	I	Frontonasal process	Neural crest
Lacrimal bone	I	Frontonasal process	Neural crest
Vomer	I	Frontonasal process	Neural crest
Ethmoid (part)	E	Frontonasal process	Neural crest
Inferior nasal concha	E	Frontonasal process	Neural crest
Maxilla	I	1st arch	Neural crest
Zygomatic bone	I	1st arch	Neural crest
Mandible	I	1st arch	Neural crest
Palatine bone	I	1st arch	Neural crest
Temporal bone (tympanic ring)	I	1st arch	Neural crest
Sphenoid (pterygoid)	I	1st arch	Neural crest
Malleus	E	1st arch	Neural crest
Incus	E	1st arch	Neural crest
Hyoid (superior body, lesser horn)	E	2nd arch	Neural crest
Temporal (styloid)	E	2nd arch	Neural crest
Stapes	E	2nd arch	Neural crest
Hyoid (inferior body, greater horn)	E	3rd arch	Neural crest
<i>Membranous neurocranium</i>			
Greater wings of sphenoid (lateral)	I		Neural crest
Frontal	I		Neural crest
Squamous temporal	I		Neural crest
Parietal	I		Paraxial mesoderm
Supranuchal squamous occipital	I		Paraxial mesoderm
<i>Cartilaginous neurocranium</i>			
Ethmoid (part)	E		Neural crest
Sphenoid (lesser wing)	E		Neural crest
Sphenoid (body)	E		Paraxial mesoderm
Occipital (base)	E		Paraxial mesoderm
Temporal	E		Paraxial mesoderm
Sphenoid (greater wing, medial)	E		Neural crest
Infranuchal squamous occipital	E		Paraxial mesoderm

*Abbreviations:* I, intramembranous; E, endochondral.  
*Note:* Tubular (long) bones undergo endochondral ossification. The clavicle is the only exception. Congenital defects of intramembranous ossification therefore affect both the skull and clavicle (cleidocranial dysostosis).

Fig. 2.4 Sutures in the adult skull

A Left lateral view.

B Superior view.

Synostosis (the fusion of the cranial bones along the sutures) occurs during adulthood. Although the exact times of closure vary,

the order (sagittal, coronal, lambdoid) does not. Closure of each fontanelle yields a particular junction (see Table 2.1). Premature closure of the cranial sutures produces characteristic deformities (see Fig. 2.11, p. 22).

## Skull: Lateral View

**Fig. 2.5 Cranial bones**  
Left lateral view.

**Fig. 2.6 Skull (cranium)**

Left lateral view. This view displays the greatest number of cranial bones (indicated by different colors in **Fig. 2.5**). The zygomatic arch is

formed by the zygomatic process of the temporal bone and the temporal process of the zygomatic bone, which are united by an oblique suture.

## Skull: Anterior View

**Fig. 2.7 Cranial bones.**  
Anterior view.

**Fig. 2.8 Le Fort classification of midfacial fractures**

The framelike construction of the facial skeleton leads to characteristic patterns of fracture lines in the midfacial region (Le Fort I, II, and III).

**Le Fort I:** This fracture line runs across the maxilla and above the hard palate. The maxilla is separated from the upper facial skeleton, disrupting the integrity of the maxillary sinus (*low transverse fracture*).

**Le Fort II:** The fracture line passes across the nasal root, ethmoid bone, maxilla, and zygomatic bone, creating a *pyramid fracture* that disrupts the integrity of the orbit.

**Le Fort III:** The facial skeleton is separated from the base of the skull. The main fracture line passes through the orbits, and the fracture may additionally involve the ethmoid bones, frontal sinuses, sphenoid sinuses, and zygomatic bones.

**Fig. 2.9 Skull**

Anterior view. The boundaries of the facial skeleton (viscerocranium) can be clearly appreciated in this view. The bony margins of the anterior nasal aperture mark the start of the respiratory tract in the skull. The nasal cavity, like the orbits, contains a sensory organ (the olfac-

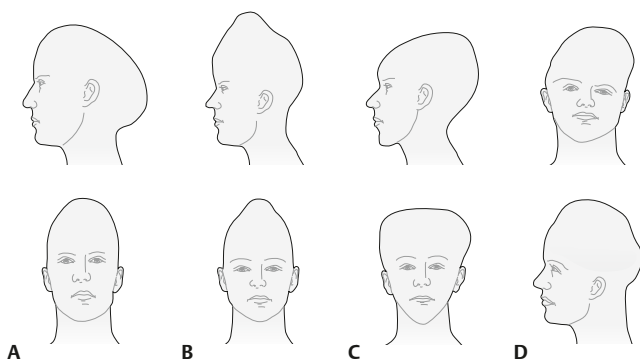

tory mucosa). The *paranasal sinuses* are shown schematically in **Fig. 7.8**, p. 187. The anterior view of the skull also displays the three clinically important openings through which sensory nerves pass to supply the face: the supraorbital foramen, infraorbital foramen, and mental foramen.

## Skull: Posterior View

**Fig. 2.10 Cranial bones.**  
Posterior view.

**Fig. 2.11 Premature closure of cranial sutures**

The premature closure of a cranial suture (craniosynostosis) may lead to characteristic cranial deformities:

- A** Sagittal suture: scaphocephaly (long, narrow skull).
- B** Coronal suture: oxycephaly (pointed skull).
- C** Frontal suture: trigonocephaly (triangular skull).
- D** Asymmetrical suture closure, usually involving the coronal suture: plagiocephaly (asymmetric skull).

**Fig. 2.12 Hydrocephalus and microcephaly**

- A Hydrocephalus:** When the ventricles become dilated due to cerebrospinal fluid (CSF) accumulation *before* the cranial sutures ossify, the neurocranium will expand, whereas the facial skeleton remains unchanged.
- B Microcephaly:** Premature closure of the cranial sutures or decreased growth of brain results in a small neurocranium with relatively large orbits.

**Fig. 2.13 Skull**

Posterior view. The occipital bone, which is dominant in this view, articulates with the parietal bones, to which it is connected by the lambdoid suture. Wormian (sutural) bones are isolated bone plates often found

in the lambdoid suture. The cranial sutures are a special type of syndesmosis (i.e., ligamentous attachments that ossify with age). The outer surface of the occipital bone is contoured by muscular origins and insertions: the inferior, superior, median, and supreme nuchal lines.

## Calvaria

**Fig. 2.14 Bones of the calvaria**  
External surface, superior view.

**Fig. 2.15 The scalp and calvaria**

The three-layered calvaria consists of the outer table, the diploë, and the inner table. The diploë has a spongy structure and contains red (blood-forming) bone marrow. With a plasmacytoma (malignant transformation of certain white blood cells), many small nests of tumor cells may destroy the surrounding bony trabeculae, and radiographs will demonstrate multiple lucent areas ("punched-out lesions") in the skull.

**Fig. 2.16 Sensitivity of the inner table to trauma**

The inner table of the calvaria is very sensitive to external trauma and may fracture even when the outer table remains intact.

**Fig. 2.17 External and internal surface of the calvaria**

The external surface of the calvaria (**A**) is relatively smooth, unlike its internal surface (**B**). It is defined by the frontal, parietal, and occipital bones, which are interconnected by the coronal, sagittal, and lambdoid sutures. The smooth external surface is interrupted by the parietal foramina, which gives passage to the parietal emissary veins (see **Fig. 3.24**, p. 71). The internal surface of the calvaria bears a number of pits and grooves:

- Granular foveolae (small pits in the inner surface of the skull caused by saccular protrusions of the arachnoid membrane [arachnoid granulations] covering the brain)
- Groove for the superior sagittal sinus (a dural venous sinus of the brain, see **Fig. 3.22**, p. 70)
- Arterial grooves (which mark the positions of the arterial vessels of the dura mater, such as the middle meningeal artery, which supplies most of the dura mater and overlying bone)
- Frontal crest (which gives attachment to the falx cerebri, a sickle-shaped fold of dura mater between the cerebral hemispheres).

## Skull Base: Exterior

**Fig. 2.18 Bones of the skull base**

External surface, inferior view. The base of the skull is composed of a mosaic-like assembly of various bones.

**Fig. 2.19 Skull base**

External surface, inferior view. Note the openings that transmit nerves and vessels. With abnormalities of bone growth, these openings may remain too small or may become narrowed, compressing the neuro-

vascular structures that pass through them. The symptoms associated with these lesions depend on the affected opening. All of the structures depicted here will be considered in more detail in subsequent pages.

## Skull Base: Interior

**Fig. 2.20** Bones of the skull base  
Internal surface, superior view.

**Fig. 2.21** The cranial fossae

**A** Skull base, internal surface, superior view. **B** Skull base, midsagittal section. The interior of the skull base is deepened to form three successive fossae: the anterior, middle, and posterior cranial fossae. These depressions become progressively deeper in the frontal-to-occipital direction, forming a terraced arrangement that is displayed most clearly in **B**.

The cranial fossae are bounded by the following structures:

- Anterior to middle: lesser wings of the sphenoid bone and the jugum sphenoidale
- Middle to posterior: superior border (ridge) of the petrous part of the temporal bone and the dorsum sellae

**Fig. 2.22** Common fracture lines of skull base

Internal surface, superior view. In response to masticatory pressures and other mechanical stresses, the bones of the skull base are thickened to form “pillars” along the principal lines of force. The intervening areas that are not thickened are sites of predilection for bone fractures, resulting in the typical patterns of skull base fracture lines shown here in red. An analogous phenomenon of typical fracture lines is found in the midfacial region (see the anterior views of Le Fort fractures on p. 20).

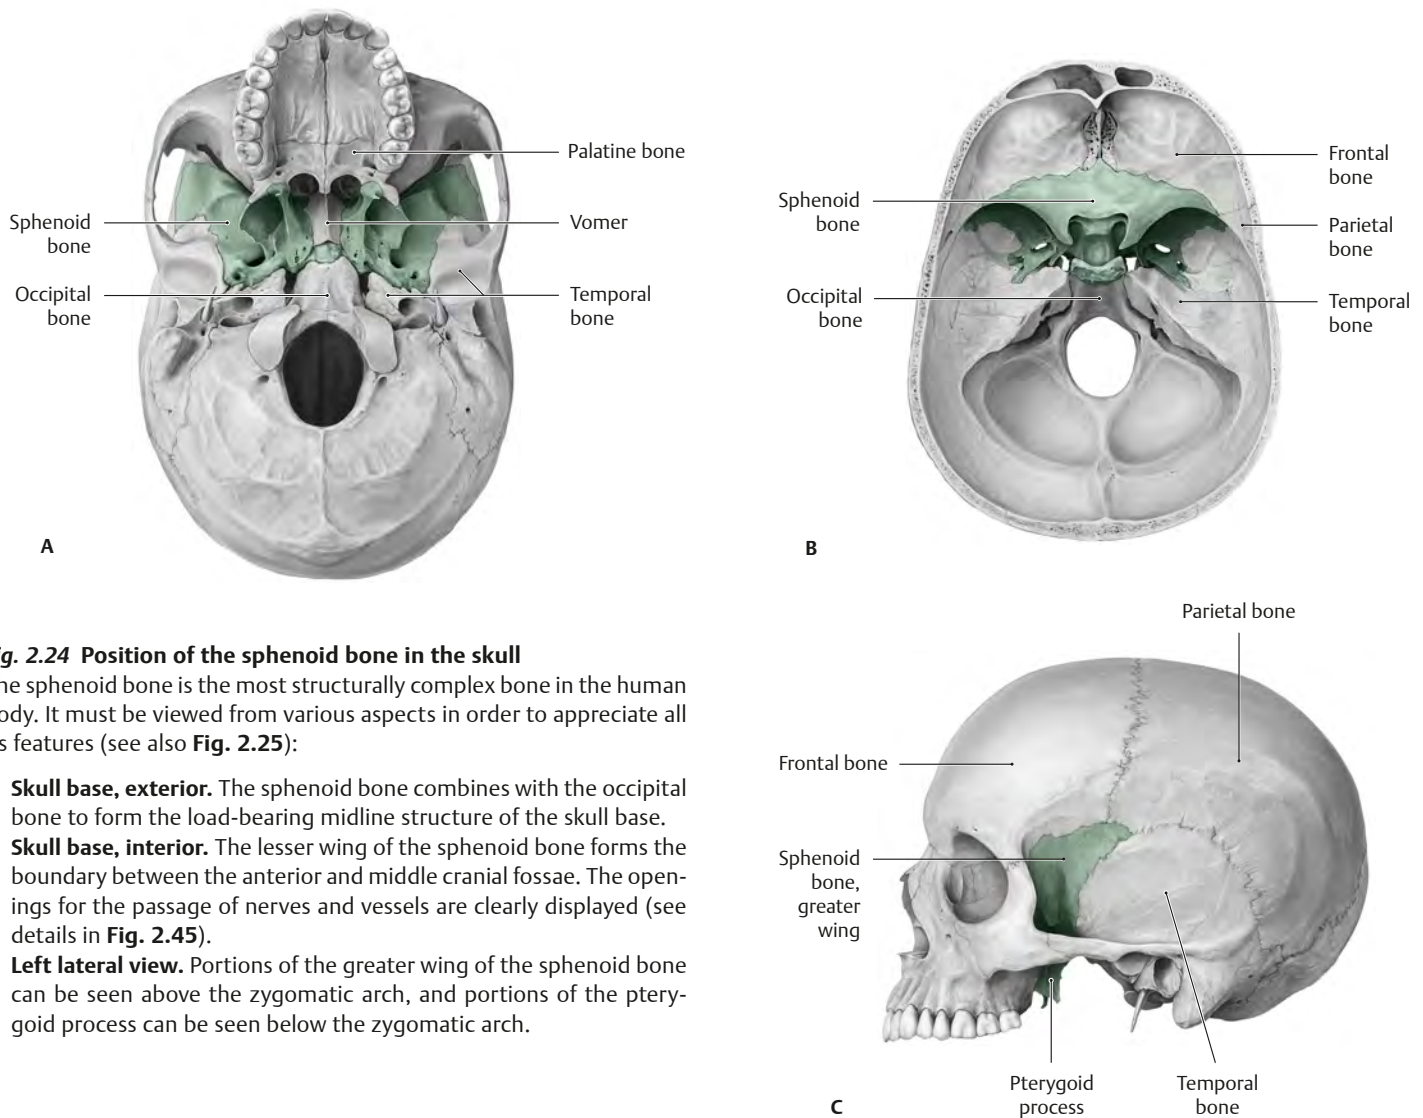

**Fig. 2.23 Skull base**

Internal surface, superior view. The openings in the interior of the base of the skull do not always coincide with the openings visible on the exterior because some neurovascular structures change direction when passing through the bone or pursue a relatively long intraosseous course. An example of this is the internal acoustic meatus, through which the facial nerve, among other structures, passes from the interior of the skull into the petrous part of the temporal bone. Most of its fibers then leave the petrous bone through the stylomastoid foramen, which is visible from the external aspect (see **Fig. 4.87**, p. 137, and **Fig. 2.45**, p. 44, for further details).

In learning the sites where neurovascular structures pass through the base of the skull, it is helpful initially to note whether these sites are located in the anterior, middle, or posterior cranial fossa. The arrangement of the cranial fossae is shown in **Fig. 2.21** (page 28).

The cribriform plate of the ethmoid bone connects the nasal cavity with the anterior cranial fossa and is perforated by numerous foramina for the passage of the olfactory fibers (see **Fig. 7.22**, p. 192). *Note:* Because the bone is so thin in this area, a frontal head injury may easily fracture the cribriform plate and lacerate the dura mater, allowing cerebrospinal fluid (CSF) to enter the nose. This poses a risk of meningitis, as bacteria from the nonsterile nasal cavity may enter the sterile CSF.

## Sphenoid Bone

**Fig. 2.24 Position of the sphenoid bone in the skull**

The sphenoid bone is the most structurally complex bone in the human body. It must be viewed from various aspects in order to appreciate all its features (see also Fig. 2.25):

- A Skull base, exterior.** The sphenoid bone combines with the occipital bone to form the load-bearing midline structure of the skull base.
- B Skull base, interior.** The lesser wing of the sphenoid bone forms the boundary between the anterior and middle cranial fossae. The openings for the passage of nerves and vessels are clearly displayed (see details in Fig. 2.45).
- C Left lateral view.** Portions of the greater wing of the sphenoid bone can be seen above the zygomatic arch, and portions of the pterygoid process can be seen below the zygomatic arch.

**Fig. 2.25 Isolated sphenoid bone**

- A Inferior view** (its position in situ is shown in Fig. 2.24). This view demonstrates the medial and lateral plates of the pterygoid process. Between them is the pterygoid fossa, which is occupied by the medial pterygoid muscle. The foramen spinosum and foramen ovale provide pathways through the base of the skull (see also in C).
- B Anterior view.** This view illustrates why the sphenoid bone was originally called the spheoid bone (“wasp bone”) before a transcription error turned it into the sphenoid (“wedge-shaped”) bone. The apertures of the sphenoid sinus on each side resemble the eyes of the wasp, and the pterygoid processes of the sphenoid bone form its dangling legs, between which are the pterygoid fossae. This view also displays the superior orbital fissure, which connects the middle cranial fossa with the orbit on each side. The two sphenoid sinuses are separated by an internal septum (see Fig. 7.11, p. 187).

- C Superior view.** The superior view displays the sella turcica, whose central depression, the hypophyseal fossa, contains the pituitary gland. The foramen spinosum, foramen ovale, and foramen rotundum can be identified.
- D Posterior view.** The superior orbital fissure is seen clearly in this view, whereas the optic canal is almost completely obscured by the anterior clinoid process. The foramen rotundum is open from the middle cranial fossa to the pterygopalatine fossa of the skull (the foramen spinosum is not visible in this view; compare with A). Because the sphenoid and occipital bones fuse together during puberty (“tribasilar bone”), a suture is no longer present between the two bones. The cancellous trabeculae are exposed and have a porous appearance.

## Temporal Bone

**Fig. 2.27 Temporal bone in the skull**

**A** Internal view. **B** Inferior view.

The temporal bone, develops from four centers that fuse to form a single bone:

- The *squamous part* (light green) includes the articular fossa (mandibular [glenoid] fossa) of the temporomandibular joint (TMJ).

**Fig. 2.26 Position of the temporal bone in the skull**

Left lateral view. The temporal bone is a major component of the base of the skull. It forms the capsule for the auditory and vestibular apparatus and bears the articular fossa of the temporomandibular joint (TMJ).

- The *petromastoid part* (pale green) contains the auditory and vestibular apparatus.
- The *tympanic part* (darker green) forms large portions of the external auditory canal.
- The *styloid process* develops from cartilage derived from the second pharyngeal arch and is a site of muscle attachment.

**Fig. 2.28 Projection of clinically important structures onto the left temporal bone**

The tympanic membrane is shown translucent in this lateral view. Because the petrous bone contains the middle and inner ear and the tympanic membrane, a knowledge of its anatomy is of key importance in otological surgery. The internal surface of the petrous bone has openings (see **Fig. 2.29**) for the passage of the facial nerve, internal carotid artery, and internal jugular vein. A fine nerve, the chorda tympani, passes through the tympanic cavity and lies medial to the tympanic membrane. The chorda tympani arises from the facial nerve, which is susceptible to injury during surgical procedures. The mastoid process of the petrous bone forms air-filled chambers, the mastoid cells, that vary greatly in size. Because these chambers communicate with the middle ear, which in turn communicates with the nasopharynx via the pharyngotympanic (auditory or Eustachian) tube, bacteria in the nasopharynx may pass up the pharyngotympanic tube and gain access to the middle ear. From there they may pass to the mastoid air cells and finally enter the cranial cavity, causing meningitis.

**Fig. 2.29 Left temporal bone**

**A Lateral view.** An emissary vein passes through the mastoid foramen (external orifice shown in **A**, internal orifice in **C**), and the chorda tympani passes through the medial part of the petrotympanic fissure. The mastoid process develops gradually in life due to traction from the sternocleidomastoid muscle and is pneumatized from the inside (see **Fig. 2.28**).

**B Inferior view.** The shallow articular fossa of the temporomandibular joint, the mandibular (glenoid) fossa, is clearly seen from the inferior view. The facial nerve emerges from the base of the skull through

the stylomastoid foramen. The initial part of the superior jugular bulb is adherent to the jugular fossa, and the internal carotid artery passes through the carotid canal to enter the skull.

**C Medial view.** This view displays the internal orifice of the mastoid foramen and the internal acoustic meatus. The facial nerve and vestibulocochlear nerve are among the structures that pass through the internal meatus to enter the petrous bone. The part of the petrous bone shown here is also called the *petrous pyramid*, whose apex (often called the “petrous apex”) lies on the interior of the base of the skull.

## Occipital Bone & Ethmoid Bone

**Fig. 2.30** Position of the occipital bone in the exterior skull base  
Inferior view.

**Fig. 2.31** Isolated occipital bone

**A Inferior view.** This view shows the basilar part of the occipital bone, whose anterior portion is fused to the sphenoid bone. The condylar canal terminates posterior to the occipital condyles, and the hypoglossal canal passes superior and opens anterior to the occipital condyles. The condylar canal is a venous channel that begins in the sigmoid sinus and ends in the occipital vein. The hypoglossal canal contains a venous plexus in addition to the hypoglossal nerve (CN XII). The pharyngeal tubercle gives attachment to the pharyngeal raphe, and the external occipital protuberance provides a palpable bony landmark on the occiput.

**B Left lateral view.** The extent of the occipital squama, which lies above the foramen magnum, is clearly appreciated in this view. The internal openings of the condylar canal and hypoglossal canal are visible along with the jugular process, which forms part of the wall of the jugular foramen (see p. 27).

**C Internal surface.** The grooves for the dural venous sinuses of the brain can be identified in this view. The cruciform eminence overlies the confluence of the superior sagittal sinus and transverse sinuses. The configuration of the eminence shows that in some cases the sagittal sinus drains predominantly into the left transverse sinus.

**Fig. 2.32 Position of the ethmoid bone in the interior skull base**  
Superior view. The superior part of the ethmoid bone forms part of the anterior cranial fossa, and its inferior portions contribute structurally to the nasal cavities and orbit. The ethmoid bone is bordered by the frontal and sphenoid bones.

**Fig. 2.33 Position of the ethmoid bone in the facial skeleton**  
Anterior view. The ethmoid bone is the central bone of the nose and paranasal sinuses. It also forms the medial wall of each orbit.

**Fig. 2.34 Isolated ethmoid bone**

**A Superior view.** This view demonstrates the crista galli, which gives attachment to the falx cerebri and the horizontally directed cribriform plate. The cribriform plate is perforated by foramina through which the olfactory fibers pass from the nasal cavity into the anterior cranial fossa (see Fig. 7.22, p. 192). With its numerous foramina, the cribriform plate is a mechanically weak structure that fractures easily in response to trauma. This type of fracture is manifested clinically by CSF leakage from the nose (“runny nose” in a patient with head injury).

**B Anterior view.** The anterior view displays the midline structure that separates the two nasal cavities: the perpendicular plate. Note also the middle nasal concha, which is part of the ethmoid bone (of the conchae, only the inferior nasal concha is a separate bone), and the ethmoid cells, which are clustered on both sides of the middle conchae.

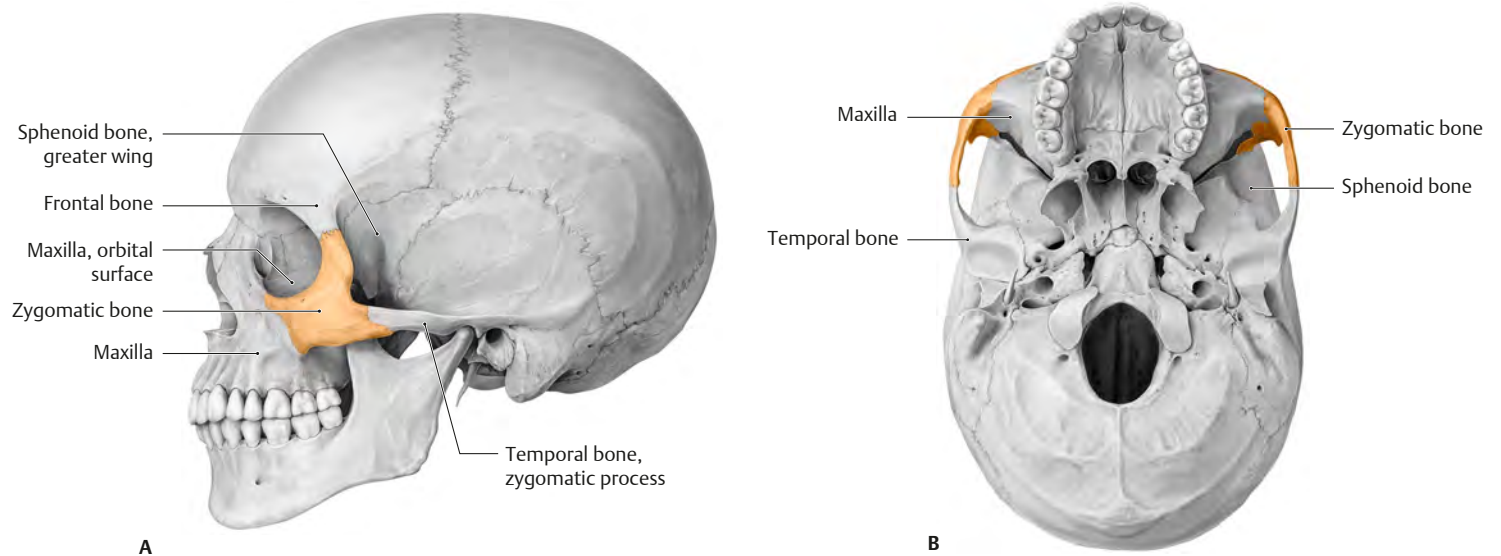

**C Left lateral view.** Viewing the bone from the left side, we observe the perpendicular plate and the opened anterior ethmoid cells. The orbit is separated from the ethmoid cells by a thin sheet of bone called the orbital plate.

**D Posterior view.** This is the only view that displays the uncinate process, which is almost completely covered by the middle concha when in situ. It partially occludes the entrance to the maxillary sinus, the semilunar hiatus, and it is an important landmark during endoscopic surgery of the maxillary sinus. The narrow depression between the middle concha and uncinate process is called the ethmoid infundibulum. The frontal sinus, maxillary sinus, and anterior ethmoid air cells open into this “funnel.” The superior concha is located at the posterior end of the ethmoid bone.

## Zygomatic (Malar) Bone & Nasal Bone

**Fig. 2.35 Zygomatic bone in the skull**

**A** Left lateral view. **B** Inferior view.

The zygomatic (malar) bone, or zygoma, is important in determining the width and morphology of the face and is a major buttress between the maxilla and the skull. In addition, it forms a significant portion of the floor and lateral walls of the orbit. The zygoma contains foramina that transmit the zygomaticofacial and zygomaticotemporal

arteries and the corresponding nerves (from the maxillary nerve [CN V<sub>2</sub>]). Muscles that attach along the zygomatic arch include the masseter, zygomaticus major, and some fibers of the temporalis fascia. The Whitnall tubercle, which is the attachment site for the lateral canthal tendon, is located on the zygoma. This tendon is crucial in maintaining the contour of the eye.

**Fig. 2.36 Isolated zygomatic bone**

**A** Inferior view. **B** Left lateral view.

The zygoma is a substantial bone but its prominent position on the face leaves it vulnerable to fracture following trauma. Trauma that transmits minimal force to the zygoma may cause a non-displaced fracture at the suture lines. Greater force, for example, following a motor vehicle accident, will result in displacement of the bone and involvement of the orbital rim and floor, the zygomaticofrontal suture, the zygomaticomaxillary buttress, and the zygomatic arch. Symptoms of zygoma fracture include pain, facial bruising and swelling, a flattened malar eminence, diplopia (double vision), trismus (lock jaw), and al-

tered mastication (due to masseteric spasm or interference of the normal mechanism of the coronoid process by bony fragments), loss of sensation below the orbit (due to infraorbital nerve involvement), and ipsilateral epistaxis (nosebleed) (due to laceration of the mucosa of the maxillary sinus). Nondisplaced fractures do not require treatment. Displaced fractures commonly require open reduction and fixation, with reconstruction of the orbit. Displacement of the zygomatic arch may be reduced by the Gillies technique, in which an incision is made over the temporalis muscle and an instrument is slid under the arch and hooked and the arch is elevated into its normal position.

**Fig. 2.37 Nasal bone in the skull**

Anterior view.

Fractures of the nasal bones are common following facial trauma, for example, motor vehicle accidents, sports injuries, or fights. This is due both to the prominence of the nose and the fragility of the nasal bones. Symptoms of nasal fractures include pain, bruising, swelling, epistaxis

(nosebleeds), and deformity of the nose. The patient may also experience difficulty breathing. Minor nasal fractures require no treatment while those that cause deformity will require manual realignment. More severe nasal fractures, for example, those involving the nasal septum or other facial bones will require surgery.

## Maxilla & Hard Palate

**Fig. 2.38 Maxilla and hard palate in skull**  
**A** Anterior view. **B** Exterior of skull base, inferior view.

**Fig. 2.39 Isolated maxilla**  
**A** Anterior view. **B** Left lateral view.

**Fig. 2.40 Bones of the hard palate**

**A** Superior view. The upper part of the maxilla is removed. The floor of the nasal cavity shown here and the roof of the oral cavity (B) are formed by the union of the palatine processes of the two maxillary bones with the horizontal plates of the two palatine bones. Cleft palate results from a failed fusion of the palatine processes at the median palatine suture (see p. 15).

**B** Inferior view. The nasal cavity communicates with the nasopharynx via the choanae, which begin at the posterior border of the hard palate. The two nasal cavities communicate with the oral cavity via the incisive canals (A), which combine and emerge at the incisive foramen.

**C** Oblique posterior view. This view illustrates the close anatomic relationship between the oral and nasal cavities. Note: The pyramidal process of the palatine bone is integrated into the lateral pterygoid plate of the sphenoid bone. The palatine margin of the vomer articulates with the hard palate along the nasal crest.

Tori are bony exostoses (lumps) that can be found on both jaws. Torus palatinus occurs in the center of the hard palate; torus mandibularis occurs in the lingual premolar or molar region of the mandible. Tori are completely benign but may cause problems for denture retention, in which case they can be surgically excised.

## Mandible & Hyoid Bone

**Fig. 2.41 Mandible**

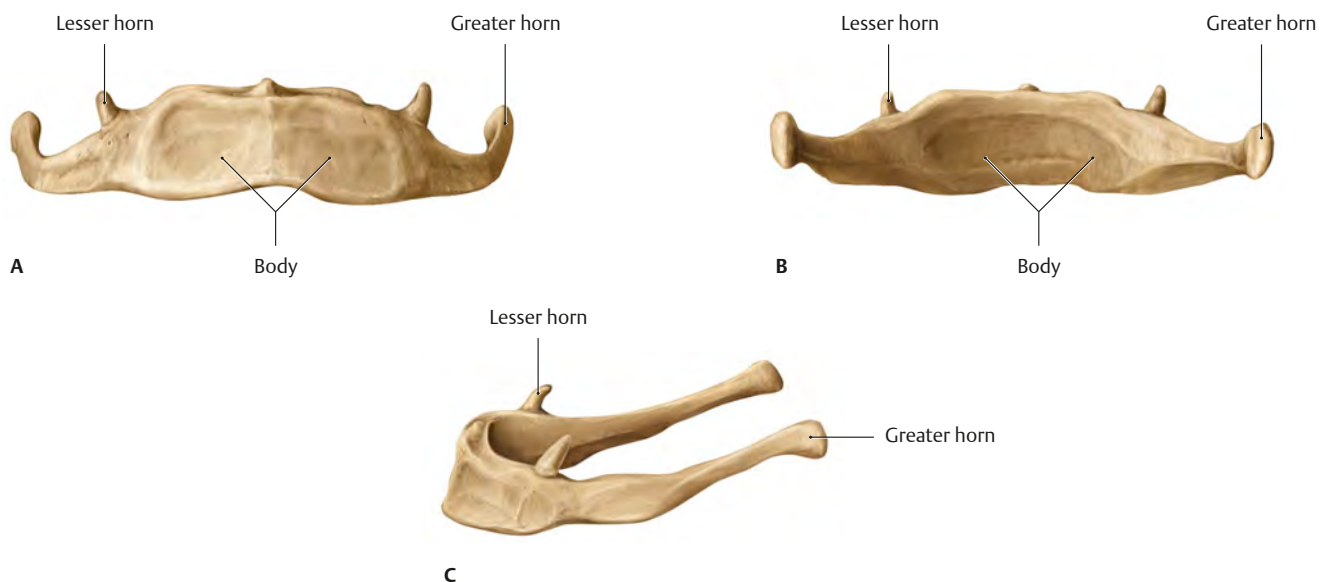

**A Anterior view.** The mandible is connected to the viscerocranium at the temporomandibular joint, whose convex surface is the head of the mandibular condyle. This “head of the mandible” is situated atop the vertical (ascending) ramus of the mandible, which joins with the body of the mandible at the mandibular angle. The teeth are set in the alveolar processes (alveolar part) along the upper border of the mandibular body. This part of the mandible is subject to typical age-related changes as a result of dental development (see Fig. 2.43). The mental branch of the trigeminal nerve exits through the mental foramen. The location of this foramen is important in clinical examinations, as the tenderness of the nerve to pressure can be tested at that location.

**B Posterior view.** The mandibular foramen is particularly well displayed in this view. It transmits the inferior alveolar nerve, which supplies sensory innervation to the mandibular teeth. Its terminal

branch emerges from the mental foramen. The mandibular foramen and the mental foramen are interconnected by the mandibular canal.

**C Oblique left lateral view.** This view displays the coronoid process, the condylar process, and the mandibular notch between them. The coronoid process is a site for muscular attachments, and the condylar process bears the head of the mandible, which articulates with the articular disk in the mandibular (glenoid) fossa of the temporal bone. A depression on the medial side of the condylar process, the pterygoid fovea, gives attachment to portions of the lateral pterygoid muscle.

**D Superior view.** This view displays the retromolar fossa, retromolar triangle, and buccal shelf. The retromolar fossa is the insertion point for some fibers of the temporalis muscle. Lower dentures should be designed to avoid this area so that they are not dislodged during mastication. The buccal shelf (as a primary bearer of stress) and the retromolar triangle are areas that are utilized to provide support for lower dentures.

**Fig. 2.42 Hyoid bone**

**A** Anterior view. **B** Posterior view. **C** Oblique left lateral view. The hyoid bone is suspended by muscles and ligaments between the oral floor

and the larynx. The greater horn and body of the hyoid bone are palpable in the neck. The physiological movement of the hyoid bone can be palpated during swallowing.

## Mandible: Age-related Changes & Mandibular Fractures

**Fig. 2.43 Age-related changes in the mandible**

The structure of the mandible is greatly influenced by the alveolar process the teeth. Because the angle of the mandible adapts to changes in the alveolar process, the angle between the body and ramus also varies with age-related changes in the dentition. The angle measures approximately 150 degrees at birth and approximately 120 to 130 degrees in adults, decreasing to 140 degrees in the edentulous mandible of old age.

- A At birth** the mandible is without teeth, and the alveolar process has not yet formed.
- B In children** the mandible bears the deciduous teeth. The alveolar process is still relatively poorly developed because the deciduous teeth are considerably smaller than the permanent teeth.
- C In adults** the mandible bears the permanent teeth, and the alveolar process is fully developed.
- D In old age**, the mandible can be edentulous (toothless), with accompanying resorption of the alveolar process.

*Note:* The resorption of the alveolar process with age leads to a change in the position of the mental foramen (which is normally located below the second premolar tooth, as in **C**). This change must be taken into account in surgery or dissections involving the mental nerve. The alveolar process is the portion of the maxilla and mandible that supports the roots of the teeth. It is composed of two parts, the alveolar bone proper and the supporting bone. The alveolar bone proper lines the tooth sockets (alveoli). Supporting bone consists of cortical plates of compact bone on the inner and outer surfaces of the maxilla and mandible and the intervening spongy bone between the cortical plates and alveolar bone proper. Alveolar bone is subject to resorption following tooth loss (a normal physiological process) and in certain disease states (e.g., abscess formation, cysts, osteoporosis). Basal bone is that portion of the maxilla and mandible deep to the alveolar bone. It is not subject to resorption.

**Fig. 2.44 Mandibular fracture**

Anterior view. **A** Mandibular fracture. **B** Reduction and fixation of mandibular fracture. Mandibular fracture is a common injury, for example, following motor vehicle accidents, fights, or sporting accidents, due to the prominence of the mandible and its relative lack of support. Most fractures occur in the body (~30%), condyle (~25%), angle (~25%), and symphysis (~17%). To avoid misdiagnosis of the injury, the history should include not just information about the current injury but information about previous mandibular trauma or temporomandibular joint (TMJ) dysfunction. Determine the patency of the airway and the presence of other injuries (facial lacerations, swellings, or hematomas). Inspect intraoral tissues for bruising, which, if present, is suggestive of a fracture of the body or symphysis. Palpate the mandible from the symphysis to the angle, noting any swelling, tenderness, or step deformities. Next palpate the condyle through the external acoustic meatus; tenderness may indicate a fracture at this site. Note any deviation on opening the mouth. With condylar fractures, the mandible deviates toward the side of the fracture. Note also any obstruction to

mouth opening, e.g., trismus (lock jaw due to spasm of the muscles of mastication) or impaction of the coronoid process. Now evaluate the occlusion. If the teeth do not occlude as normal, this is highly suggestive of mandibular fracture, although this can also occur following tooth subluxation (loosening) or TMJ injury. Note any areas of altered sensation (paresthesia, dysesthesia, or anesthesia). The latter is suggestive of a fracture distal to the mandibular foramen. Following this, the mandible should be grasped at either side of the suspected fracture and gently manipulated to assess mobility. Confirm the diagnosis via either radiography or CT scans. Treat with antibiotics to prevent infection, followed by reduction (to the patient's normal occlusion) and surgical fixation of the fracture. The fixation method depends on many factors including the type and site of fracture and may involve the use of bars, wires, or plates for intermaxillary fixation.

The double mandibular fracture shown here is treated in a two-step process. First, the fracture at the midline is fixated with metal plates followed by the angle fracture. Note that two plates provide much more stability than a single plate.
